Package 'relliptical'

February 7, 2024

Type Package

Title The Truncated Elliptical Family of Distributions

Version 1.3.0

Description It offers random numbers generation from members of the truncated multivariate elliptical family of distribution such as the truncated versions of the Normal, Student-t, Laplace, Pearson VII, Slash, Logistic, among others. Particular distributions can be provided by specifying the density generating function. It also computes the first two moments (covariance matrix as well) for some particular distributions.

mvtelliptical	*Mean and Variance for Truncated Multivariate Elliptical Distributions*

Description

This function approximates the mean vector and variance-covariance matrix for some specific truncated elliptical distributions. The argument dist sets the distribution to be used and accepts the values Normal, t, Laplace, PE, PVII, Slash, and CN, for the truncated Normal, Student-t, Power Exponential, Pearson VII, Slash, and Contaminated Normal distribution, respectively. Moments are computed through Monte Carlo method for the truncated variables and using properties of the conditional expectation for the non-truncated variables.

Usage

```
mvtelliptical(lower, upper = rep(Inf, length(lower)), mu = rep(0,
  length(lower)), Sigma = diag(length(lower)), dist = "Normal",
  nu = NULL, n = 10000, burn.in = 0, thinning = 3)
```

Arguments

lower	vector of lower truncation points of length p.
upper	vector of upper truncation points of length p.
mu	numeric vector of length p representing the location parameter.
Sigma	numeric positive definite matrix with dimension pxp representing the scale parameter.
dist	represents the truncated distribution to be used. The values are 'Normal', 't', 'Laplace', 'PE', 'PVII', 'Slash', and 'CN' for the truncated Normal, Student-t, Laplace, Power Exponential, Pearson VII, Slash, and Contaminated Normal distributions, respectively.
nu	additional parameter or vector of parameters depending on the density generating function. See Details.
n	number of Monte Carlo samples to be generated.
burn.in	number of samples to be discarded as a burn-in phase.
thinning	factor for reducing the autocorrelation of random points.

Details

This function also considers the univariate case. The argument nu is a parameter or vector of parameters depending on the density generating function (DGF). For the truncated Student-t, Power Exponential, and Slash distribution, nu is a positive number. For the truncated Pearson VII, nu is a vector with the first element greater than $p/2$ and the second element a positive number. For the truncated Contaminated Normal distribution, nu is a vector of length 2 assuming values between 0 and 1.

Value

It returns a list with three elements:

EY	the mean vector of length p.
EYY	the second moment matrix of dimensions pxp.
VarY	the variance-covariance matrix of dimensions pxp.

Note

The Normal distribution is a particular case of the Power Exponential distribution when nu = 1. The Student-t distribution with ν degrees of freedom results from the Pearson VII distribution when nu = $((\nu+p)/2, \nu)$.

In the Student-t distribution, if nu >= 300, the Normal case is considered. For Student-t distribution, the algorithm also supports degrees of freedom nu <= 2. For Pearson VII distribution, the algorithm supports values of m <= (p+2)/2 (first element of nu).

rtelliptical	*Sampling Random Numbers from Truncated Multivariate Elliptical Distributions*

Description

This function generates observations from a truncated multivariate elliptical distribution with location parameter mu, scale matrix Sigma, lower and upper truncation points lower and upper via Slice Sampling algorithm with Gibbs sampler steps.

Usage

```
rtelliptical(n = 10000, mu = rep(0, length(lower)),
  Sigma = diag(length(lower)), lower, upper = rep(Inf, length(lower)),
  dist = "Normal", nu = NULL, expr = NULL, gFun = NULL,
  ginvFun = NULL, burn.in = 0, thinning = 1)
```

Arguments

n	number of observations to generate. Must be an integer >= 1.
mu	numeric vector of length p representing the location parameter.

Sigma	numeric positive definite matrix with dimension pxp representing the scale parameter.
lower	vector of lower truncation points of length p.
upper	vector of upper truncation points of length p.
dist	represents the truncated distribution to be used. The values are `'Normal'`, `'t'`, `'Laplace'`, `'PE'`, `'PVII'`, `'Slash'`, and `'CN'` for the truncated Normal, Student-t, Laplace, Power Exponential, Pearson VII, Slash, and Contaminated Normal distribution, respectively.
nu	additional parameter or vector of parameters depending on the density generating function. See Details.
expr	a character with the density generating function. See Details.
gFun	an R function with the density generating function. See Details.
ginvFun	an R function with the inverse of the density generating function defined in `gFun`. See Details.
burn.in	number of samples to be discarded as a burn-in phase.
thinning	factor for reducing the autocorrelation of random points.

Details

The `dist` argument represents the truncated distribution to be used. The values are `Normal`, `t`, `'t'`, `PE`, `PVII`, `Slash`, and `CN`, for the truncated Normal, Student-t, Laplace, Power Exponential, Pearson VII, Slash, and Contaminated Normal distribution, respectively.

The argument `nu` is a parameter or vector of parameters depending on the density generating function (DGF). For the truncated Student-t, Power Exponential, and Slash distribution, `nu` is a positive number. For the truncated Pearson VII, `nu` is a vector with the first element greater than $p/2$ and the second element a positive number. For the truncated Contaminated Normal distribution, `nu` is a vector of length 2 assuming values between 0 and 1.

This function also allows generating random numbers from other truncated elliptical distributions not specified in the `dist` argument, by supplying the density generating function (DGF) through arguments either `expr` or `gFun`. The DGF must be a non-negative and strictly decreasing function on `(0, Inf)`. The easiest way is to provide the DGF expression to argument `expr` as a character. The notation used in `expr` needs to be understood by package Ryacas0, and the environment of R. For instance, for the DGF $g(t) = e^{-t}$, the user must provide `expr = "exp(1)^(-t)"`. See that the function must depend only on variable t, and any additional parameter must be passed as a fixed value. For this case, when a character expression is provided to `expr`, the algorithm tries to compute a closed-form expression for the inverse function of $g(t)$, however, this is not always possible (a warning message is returned). See example 2.

If it was no possible to generate random samples by passing a character expression to `expr`, the user may provide a custom R function to the `gFun` argument. By default, its inverse function is approximated numerically, however, the user may also provide its inverse to the `ginvFun` argument to gain some computational time. When `gFun` is provided, arguments `dist` and `expr` are ignored.

Value

It returns a matrix of dimensions nxp with the random points sampled.

Note

The Normal distribution is a particular case of the Power Exponential distribution when nu = 1. The Student-t distribution with ν degrees of freedom results from the Pearson VII distribution when nu = $((\nu+p)/2, \nu)$.
